(54) Title: INTELLIGENT NETWORK

## (57) Abstract

Intelligent network (IN), comprising at least one Service Switching Point, SSP (2), at least one Service Control Point, SCP (3), one or more Intelligent Peripherals, IPs (5), and/or one or more Voice Response Systems, VRSs (4), which IN is capable of interacting with a PSTN or ISDN (1). The essence of the concept is an additional interface, in the form of a control member (6), between the IPs and/or VRSs on one side and the Service Control Point(s) on the other side. Such makes it possible that the (advanced) IPs and VRSs are capable of exchanging all sorts of information with the SCP, without the IPs or VRSs consequently being occupied for an extended period of time. As a result, the SCP may dispose of (additional) information which in a regular IN cannot be made available to the SCP(s).

Intelligent network.

#### BACKGROUND OF THE INVENTION

The invention relates to an intelligent network (IN), comprising at least one Service Switching Point, SSP, at least one Service Control Point, SCP, one or more Intelligent Peripherals, IPs, and/or one or more Voice Response Systems, VRSs, which IN is capable of interacting with a PSTN [= Public Switched Telephone Network] or ISDN [- Integrated Services Digital Network].

In the current implementations of IN standards (AIN 0.1, AIN 0.2, CS1 and CS2), there is only provided for playing, through IPs, announcements by VRSs and for receiving DTMF tones [DTMF = dual tone multiple-frequency]. In the current, modern IP and VRS implementations, however, there is offered much more functionality than playing a simple message and receiving DTMF tones. If it is desired to make use of said, more complex functionality, in most cases this will mean that the IP also collects more complex information on a call from the PSTN. For many services, it is of importance to switch through, after receiving said information, to a subsequent destination, the destination being determined on the basis of the information collected. Since the IP cannot return information to the SCP, however, the IP itself will always maintain control over the call and will have to carry out interpretations, if any. The consequence is that any routing-through must always be switched by way of IPs (or VRSs). In doing so, the available lines on the IPs (and VRSs) are occupied for a longer period of time, which is a major impediment for the application of modern IPs and VRSs.

#### SUMMARY OF THE INVENTION

The object of the present invention is to see to it that, contrary to the aforementioned prior art, the IP or VRS does return the information collected to the SCP; the IP or VRS may then return the call to the Service Switching Point (SSP), so that the line is vacated on the IP or VRS. On the basis of the information received, the SCP may instruct the SSP to switch the call through to another destination. To attain said envisaged object, the network according to the invention provides for a control member which, on one side, is connected to the outputs of the IPs and/or the VRSs, for recording information signals given off by said IPs and VRSs, respectively, which stem from calls from the PSTN, offered to said IPs and/or VRSs

by way of the SSP, which control member buffers the signals recorded from the IPs and VRSSs, while on the other side the control member is connected to the SCP for outputting the information signals to the SCP on behalf of the IPs and VRSSs.

5       Using the control member proposed by the invention, several IP or VRS modules may be simply coupled together within one call, without special IP-IP interfaces or lines being required. In the event of application of the concept according to the invention, the IPs or VRSSs are occupied only for the minimum period of time required. Since in  
10       this concept the SSP always activates the IPs or modules, there is no interface required between modules mutually. Combinations of modules within a service may therefore be easily realised. Thus, e.g., a module for the validation of a new credit card may be easily  
15       integrated into existing services by including a module call in the service. If modules are already in use, any desired combination with said modules is possible, without the need of adjusting the interface for existing modules.

      Since the SSP continuously sets up new outgoing calls when going through the various modules, it is possible to adopt a different rate  
20       for each module. In this case, fixing rates may take place by way of the regular SSP rate-fixing. If no use is made of the concept according to the invention, switching-through will have to be done by the IP and, as to the SSP rate-fixing, only one rate will be permitted for the entire conversation.

25       By placing a central control member on the coupling between an IP or VRS, there is realised a central interface point with which not only may there be driven SCPs but, e.g., also be written or retrieved information from external data bases. Said coupling is of particular importance for services where telephony services are combined with  
30       data services (also called Computer Telephony Integration, or CTI). An example thereof is the synchronisation of data screens towards operators having client data and the incoming calls from clients towards said operators.

      Furthermore, the concept is very flexible as various IPs (VRSSs)  
35       may be chosen for each module. Combining modules is arranged from the SCP and switched by way of the SSP. As a result, all modules may be combined in random order. If modules (having new possibilities) are later added, they may be combined, in a service, with any existing

modules. Architecture proposed:

#### EXEMPLARY EMBODIMENTS

FIG. 1 shows the "Super-IP" architecture proposed by the invention. The figure shows a PSTN/ISDN 1 and, as part of an Intelligent-network architecture, an SSP 2, to which a number of VRSS and an IP 5 are connected. The SSP is additionally connected to an SCP. According to the invention, there is mounted a control member 6 which forms a buffer and a coupling between the IPs and VRSSs and the SCP, as a result of which the SCP may be controlled by advanced control signals from modern IPs and VRSSs without, however, using said (expensive) elements any longer than strictly necessary: the output of said elements is included and buffered by the control member 6 until the SCP is capable of using said buffered information. The coupling (designated by bold lines in the figure) may therefore be used for exchanging data collected for the call. There may also be given instructions, possibly by way of the coupling by the IP, VRS or control component, to the SCP for further processing the call. By having the coupling take place by way of a central control member, there originates a central coupling point which may also be used as a bridge to the IT world, such as external IT systems and/or data bases, represented by a network 7, such as the Internet. The protocol used between the IPs and VRSSs and the control member is TCP/IP [TCP = transmission control protocol]; said protocol is also used for communication with the Internet 7. In the connection between the control member 6 and the SCP, the INAP protocol [?] is used.

The central control member 6 may also use the information from the IPs and VRSSs for driving a Computer-Telephony-Integration (CTI) coupling towards desired final destinations (determined in, or by way of, the control member and passed on to the SCP). An example thereof is a transmission pop-up data screen having client information (on the basis of signalling information received, such as the telephone number of the caller) to the final destination (operator) who in synchronisation also receives the call from the client. Within this concept, the central control member operates as a synchronisation point for the telephony and data services. Since, in this concept, the SCP and SSP will take care of the eventual switching-through of a call, there automatically arises the option of network ACD [=

Automatic Call Distributor] and CTI solutions.

The great advantages when applying the concept according to the invention are:

- 5       - There is a briefer occupation of IP and VRS line capacity since the IP or VRS need not switch through but may also return the control and the call to the SCP and the SSP. IPs and VRSs are deployed in part of the call as a result of which, within one call, more IPs and/or VRSs may be easily addressed. In addition, IP/VRS applications may be simply and flexibly combined within one service.
- 10      - The concept may be simply extended as ever more new IPs and/or VRSs may be used as modules. By applying the concept, the interface problems between IPs and/or VRSs are limited to a minimum.

15       Since for any module there are set up separate sub-conversations, there may be adopted a different rate for each module.

Synchronisation of telephony and data services is feasible using the central control member.

- 20      - Since the SCP continues to control the switching-through of the call (and not the IP, VRS or PABX [= Private Automatic Branch eXchange]), upon application of this concept network ACD and CTI solutions may be realised in a simple manner.

CLAIMS

Intelligent network (IN), comprising at least one Service  
Switching Point, SSP (2), at least one Service Control Point, SCP (3),  
one or more Intelligent Peripherals, IPs (5), and/or one or more Voice  
5 Response Systems, VRSs (4), which IN is capable of interacting with a  
PSTN or ISDN (1), characterised by a control member (6) which, on one  
side, is connected to the outputs of the IPs and VRSs, respectively,  
for including the information signals given off by said IPs and VRSs,  
respectively, which stem from calls from the PSTN or ISDN, offered to  
10 said IPs and VRSs, respectively, by way of the SSP, which control  
member buffers the signals included from the IPs and VRSs,  
respectively, while the control member is connected, on the other  
side, to the SCP for, on behalf of the IPs and VRSs, respectively,  
giving off to the SCP, control signals controlled by said information  
15 signals.
